## Chapter 10

- 1. In what ways might monopoly be more beneficial than perfect competition with regard to product safety and environmental protection?
- 2. In the wake of natural disasters like hurricanes, there is often a spike in the demand for certain necessities like ice. Anti-gouging laws limit price increases in such situations to, say, 20%. Show the effect of such statutes in the following graph, where  $D_1$  and  $D_2$  represent the pre- and post-hurricane demands. Does the law improve efficiency?

3. The graph below shows the market for tickets to a concert with a fixed supply of seats. What is the equilibrium price? Suppose the price is set at *P*<sub>0</sub>. What will be the consequence? Ticket scalping—the purchase and resale of tickets at a higher price—is illegal in some jurisdictions. What would be the effect of allowing ticket scalping in the current setting? What might the rationale be for making it illegal?

- 4. Professional sports leagues are largely exempted from anti-trust laws, which allows them to, for example, limit entry of new teams. Can you think of a rationale for this exemption? Is there a difference in the welfare effects of entry in markets for ordinary goods, as opposed to entry of new teams in a sports league?
- 5. Explain what a natural monopoly is. Why does it present a problem for anti-trust law?
- 6. In the diagram below, show the competitive output and price, and compare it to the monopoly output and price. What is the economic basis for using anti-trust law to prevent monopoly? Illustrate the gain in the graph.
